Summary

Reinforcement learning (RL) aims to learn and evaluate a sequential decision rule, often referred to as a "policy", that maximizes expected discounted cumulative rewards to optimize the population-level benefit in an environment across possibly infinitely many time steps. RL has gained popularity in fields such as healthcare, banking, autonomous driving, and, more recently, large language model fine-tuning. However, the sequential decisions made by an RL algorithm, while optimized to maximize overall population benefits, may disadvantage certain individuals who are in minority or socioeconomically disadvantaged groups. A fairness-unaware RL algorithm learns an optimal policy that makes decisions based on the *observed* state variables. However, if certain values of the sensitive attribute influence the state variables and lead the policy to systematically withhold certain actions from an individual, unfairness will result. For example, Hispanics may under-report their pain levels due to cultural factors, misleading a fairness-unaware RL agent to assign less therapist time to these individuals (Piette et al., 2023). Deployment of RL algorithms without careful fairness considerations can raise concerns and erode public trust in high-stakes settings.

To formally define and address the fairness problem in the novel sequential decision-making settings, Wang et al. (2025) extended the concept of single-stage counterfactual fairness (CF) in a structural causal framework (Kusner et al., 2018) to the multi-stage setting and proposed a data preprocessing algorithm that ensures CF. A policy is counterfactually fair if, at every time step, the probability of assigning any action does not change had the individual's sensitive attribute taken a different value, while holding constant other historical exogenous variables and actions. In this light, the data preprocessing algorithm ensures CF by constructing new state variables that are not impacted by the sensitive attribute(s). Reward preprocessing is also conducted, but with a different purpose to improve the value of the learned optimal policy rather than to ensure CF. We refer interested readers to Wang et al. (2025) for more technical details.

The `PyCFRL` library implements the data preprocessing algorithm proposed by Wang et al. (2025) and provides functionalities to evaluate the value (expected discounted cumulative reward) and counterfactual unfairness level achieved by any given policy. Here, "CFRL" stands for "Counterfactual Fairness in Reinforcement Learning". The library produces preprocessed trajectories that can be used by an off-the-shelf offline RL algorithm, such as fitted Q-iteration (FQI) (Riedmiller, 2005), to learn an optimal CF policy. The library can also simply read in any policy following a required format and return its value and counterfactual unfairness level in the environment of interest, where the environment can be either pre-specified or learned

44 from the data.

Statement of Need

46 Many existing `Python` libraries implement algorithms designed to ensure fairness in machine
47 learning. For example, `Fairlearn` (Weerts et al., 2023) and `aif360` (Bellamy et al., 2018)
48 provide tools for mitigating bias in single-stage machine learning predictions under statistical
49 association-based fairness criteria such as demographic parity and equal opportunity. However,
50 existing libraries do not focus on counterfactual fairness, which defines an individual-level
51 fairness concept from a causal perspective, and they cannot be easily extended to the general
52 RL setting. Scripts available from `ml-fairness-gym` (D'Amour et al., 2020) allow users to
53 simulate unfairness in sequential decision-making, but they neither implement algorithms that
54 reduce unfairness nor address CF. To our knowledge, Wang et al. (2025) is the first work to
55 study CF in RL. Correspondingly, `PyCFRL` is also the first code library to address CF in the RL
56 setting.

57 The contribution of `PyCFRL` is two-fold. First, `PyCFRL` implements a data preprocessing algorithm
58 that ensures CF in offline RL. For each individual in the data, the preprocessing algorithm
59 sequentially estimates and concatenates the counterfactual states under different sensitive
60 attribute values with the observed state at each time point into a new state vector. The
61 preprocessed data can then be directly used by existing RL algorithms for policy learning, and
62 the learned policy will be counterfactually fair up to finite-sample estimation accuracy. Second,
63 `PyCFRL` provides a platform for assessing RL policies based on CF. After passing in any policy
64 and a data trajectory from the environment of interest, users can estimate the value and
65 counterfactual unfairness level achieved by the policy in the environment of interest.

High-level Design

67 The `PyCFRL` library is composed of 5 major modules as summarized below.

Module	Functionalities
`reader`	Implements functions that read tabular trajectory data into an array format required by `PyCFRL`. Also implements functions that export trajectory data to the tabular format.
`preprocessor`	Implements the data preprocessing algorithm introduced in Wang et al. (2025).
`agents`	Implements an FQI algorithm (Riedmiller, 2005), which learns RL policies and makes decisions based on the learned policy.
`environment`	Implements a synthetic environment that produces synthetic data as well as a simulated environment that estimates and simulates the transition dynamics of the unknown environment underlying some real-world RL trajectory data. Also implements functions for sampling trajectories from the synthetic and simulated environments.
`evaluation`	Implements functions that evaluate the value and counterfactual unfairness level of a policy.

68 A general `PyCFRL` workflow is as follows: First, simulate trajectories using `environment` or read
69 in trajectories using `reader`. Then, train a preprocessor using `preprocessor` and preprocess the
70 training trajectory data. After that, pass the preprocessed trajectories into the FQI algorithm in
71 `agents` to learn a counterfactually fair policy. Finally, use functions in `evaluation` to evaluate
72 the value and counterfactual unfairness level of the trained policy.

73 In addition, `PyCFRL` also provides tools to check for potential non-convergence that may arise
74 during the training of neural networks, FQI, or fitted-Q evaluation (FQE). More discussions
75 about non-convergence in `PyCFRL` can be found in the "Common Issues" section of the
76 documentation.

Data Examples

78 In the "Example Workflows" section of the documentation, we provide data examples with
79 code to demonstrate some major workflows of `PyCFRL`. We also record the computing times
80 of different workflows under different combinations of the number of individuals (N) and the
81 length of horizons (T) in the "Computing Times" section of the documentation.

Conclusions

83 `PyCFRL` is a `Python` library that enables counterfactually fair reinforcement learning through
84 data preprocessing. It also provides tools to calculate the value and unfairness level of a given
85 policy. To our knowledge, it is the first library to address CF problems in the context of RL. The
86 practical utility of `PyCFRL` can be further improved via extensions. First, the current `PyCFRL`
87 implementation requires every individual in the offline dataset to have the same number of
88 time steps. Extending the library to accommodate variable-length episodes can improve its
89 flexibility and usefulness. Second, `PyCFRL` can further combine the preprocessor with popular
90 offline RL algorithm libraries such as `d3rlpy` (Seno & Imai, 2022), or connect the evaluation
91 functions with established RL environment libraries such as `gym` (Towers et al., 2024). Third,
92 generalization to non-additive counterfactual states reconstruction can make `PyCFRL` more
93 versatile. We leave these extensions to future updates.
